

Project Overview

Colton Strahan

Final Project Proposal

The application I am going to be developing is a social media app centered around media, specifically music; if everything regarding music goes well, then I will most likely introduce movies, as well as maybe video games. Essentially, this app will help users connect with others over common interests (thing songs, games, etc), and will also help users expand their current repertoire of loved music. A few core features will be liking songs (which will then add them to your profile), rating songs on a ten point scale, the ability to review and critique each individual song, as well as making posts; whether just text based, or including a song plus what you have to say about it. The target group will be just about anyone who loves music, and wants to share their love with others, as well as gain exposure to music they may have never listened to before.

The tech stack I am planning on using is

React: I am familiar with it, and have used it in prior projects/courses.

Tailwind CSS: I am familiar with it, and have used it in prior projects/courses.

Node.js: I am familiar with it, and have used it in prior projects/courses.

Express: Have not used before, but did some research, and saw it should be very good for routing and authentication.

Mongo DB: Have used in prior courses; will be very good to manage all the data.

Open AI API: The go to LLM. Will use to help provide users personal recommendations.

Docker: Ensure that the application will run properly on everyone's machine; have used previously in this class.

Google Cloud: Offers reliable hosting, have used previously in this class
